

## 1 Viscoelasticity

- Introduction to the Maxwell model
- Brief introduction to generalized standard materials

## 2 Model

- Simple RNN model without physics
- Maxwell model RNN
- GSM model RNN

## 3 Conclusion

- What were the differences?
- Which model to choose?
- How to choose the training data?

From the second law of thermodynamics we derive the Clausius-Duhem inequality:

$$\sigma \dot{\varepsilon} - \dot{e} \geq 0 \quad (1)$$

Where we mention that:

- $e = e(\varepsilon, \gamma)$ , with  $\gamma$  an internal state variable
- Change in temperature is neglected

Using the definition for  $e$ , we get:

$$\left( \sigma - \frac{\partial e}{\partial \varepsilon} \right) \dot{\varepsilon} - \frac{\partial e}{\partial \gamma} \dot{\gamma} \geq 0 \quad (2)$$

$$\Rightarrow \quad \sigma = \frac{\partial e}{\partial \varepsilon} \quad (3) \quad D = -\frac{\partial e}{\partial \gamma} \dot{\gamma} \quad (4)$$

# Theoretical model

## Maxwell model

Figure: Maxwell modell

The overall energy is defined with:

$$e = \frac{1}{2}E^\infty \varepsilon^2 + \frac{1}{2}E(\varepsilon - \gamma)^2 \quad (5)$$

We therefore get for the stress and dissipation:

$$\sigma = E^\infty \varepsilon + E(\varepsilon - \gamma) \quad (6)$$

$$D = E(\varepsilon - \gamma)\dot{\gamma} \quad (7)$$

For the evolution equation we obtain:

$$\dot{\gamma} = \tilde{f}(\varepsilon, \gamma)(\varepsilon - \gamma), \quad \tilde{f}(\varepsilon, \gamma) = \frac{E}{\eta} > 0 \quad (8)$$

# Generalized standard materials (GSM)

## A more general framework

TECHNISCHE

DARMSTADT

Now: generalized motivation for the viscoelastic model.

Introduction of thermodynamic potentials:

$$\Psi = \Psi(\mathbf{F}, \Lambda) \quad (9)$$

$$\Phi = \Phi(\mathbf{F}, \Lambda, \dot{\Lambda}) \quad (10)$$

This implies the constitutive equations:

$$\mathbf{S} = \frac{\partial \Psi(\mathbf{F}, \Lambda)}{\partial \mathbf{F}} \quad (11)$$

$$\frac{\partial \Psi(\mathbf{F}, \Lambda)}{\partial \Lambda} + \frac{\partial \Phi(\mathbf{F}, \Lambda, \dot{\Lambda})}{\partial \dot{\Lambda}} = 0 \quad (12)$$

We then identify for the 1D case  $\Lambda \rightarrow \gamma$  and  $\mathbf{F} \rightarrow \varepsilon$  and define for the dissipation:

$$\Phi(\mathbf{F}, \Lambda, \dot{\Lambda}) = \phi(\varepsilon, \gamma, \dot{\gamma}) = \frac{1}{2g(\varepsilon, \gamma)} \dot{\gamma}^2, \quad g(\varepsilon, \gamma) > 0 \quad (13)$$

Using the constitutive equation 12 , rewritten for the 1D case and the definition 13 for the dissipation energy:

$$\left( \sigma - \frac{\partial e(\varepsilon, \gamma)}{\partial \varepsilon} \right) \dot{\varepsilon} - \frac{e(\partial \varepsilon, \gamma)}{\partial \gamma} \dot{\gamma} \geq 0 \quad (14)$$

$$\Leftrightarrow \left( \sigma - \frac{\partial e(\varepsilon, \gamma)}{\partial \varepsilon} \right) \dot{\varepsilon} + \frac{\partial \phi(\varepsilon, \gamma, \dot{\gamma})}{\partial \dot{\gamma}} \dot{\gamma} = \left( \sigma - \frac{\partial e(\varepsilon, \gamma)}{\partial \varepsilon} \right) \dot{\varepsilon} + \frac{1}{g(\varepsilon, \gamma)} \dot{\gamma}^2 \geq 0 \quad (15)$$

Then, we obtain the evolution equation for  $\gamma$  from eq. 12 with:

$$\frac{\partial e(\varepsilon, \gamma)}{\partial \gamma} + \frac{1}{g(\varepsilon, \gamma)} \dot{\gamma} \Leftrightarrow \dot{\gamma} = -g(\varepsilon, \gamma) \frac{\partial e(\varepsilon, \gamma)}{\partial \gamma} \quad (16)$$

Using the overall energy  $e(\varepsilon, \gamma)$  we obtain the maxwell model:

$$\sigma = E^\infty \varepsilon + E(\varepsilon - \gamma) \quad (17)$$

$$D = -E(\varepsilon - \gamma) \dot{\gamma} \quad (18)$$

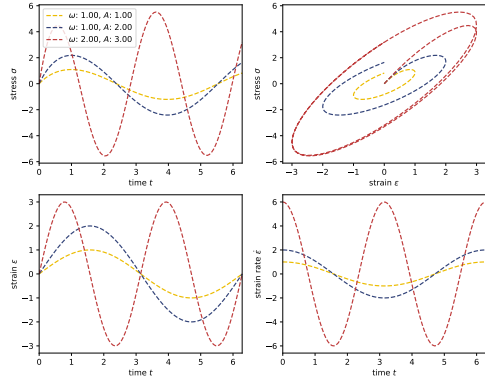

$$\dot{\gamma} = \frac{E}{\eta} (\varepsilon - \gamma) \quad (19)$$

# Training data

Used for models with 3 layers, 8 nodes, 4000 training epochs

(a) Relaxation training data

(b) Cyclic training data

# Simple RNN

## Training without physical information

Data: dashed line, model prediction: continuous line

(a) Trained on both data sets ( $\omega = 1, A = 1$ )

(b) Loss

# Simple RNN

## Training without physical information

Data: dashed line, model prediction: continuous line

## Strain energy as FFNN

Data: dashed line, model prediction: continuous line

(a) Trained on relaxation data ( $\omega \in \{1, 2\}, A \in \{1, 3\}$ )

(b) Loss

- Physics, e.g. the second law of thermodynamics can be included in RNN models
- Simple RNN models without any physics included only work for carefully chosen training data (interpolation instead of extrapolation)
- Modeling evolution equations with FFNNs works well already for only a few training data points (interpolation **and** extrapolation)
- Energy as FFNN in GSM model yields reasonable results only in interpolation cases
- ⇒ Try to model only the evolution equation whenever possible using FFNNs, otherwise model the strain energy by using a wide range of training data points
